ABSTRACT

This thesis discusses the modification of and additions to an existing Optimal Systems Control FORTRAN Program (OPTSYS) originally obtained from Professor Arthur E. Bryson of Stanford University. This program has been subsequently redesigned to run interactively on the IBM 3033 VM/CMS by Lieutenant Commander John G. Hoden, and additions by Commander Harry A. Diel provide the user with a highly accurate graphic time response to a system designed using the OPTSYSX program.

The addition of the FORTRAN program OPTGRAPH gives the user the capability to obtain classical analysis (Pole-Zero Map, Root Locus, Bode, Nyquist, and Nichols) of transfer functions, calculated for a system designed with the OPTSYSX program. The OPTGRAPH program uses high resolution precision plotting software to provide the user with highly accurate frequency response plcts.

This series of programs permits users to rapidly carry out simulation, analysis, and design of Optimal Systems Control problems in a totally interactive mode.

I. INTRODUCTION

The purpose of this thesis is to describe the modification and additions to the existing FORTRAN program (OPTSYS) which is used in the study and application of Optimal Systems Control theory.

The OPtimal SYstems control program was originally developed by Hall [Ref. 1] to support his research in rotary-wing aircraft control systems. Later program modifications were made by Walker [Ref. 2] and Liu [Ref. 3] of Stanford University, and are designated OPTSYS 4 and OPTSYS 5 respectively. OPTSYS modifications made by Hoden [Ref. 4] were primarily devoted to creating a user-friendly interactive version (OPTSYSX) of the OPTSYS 4 program. The latest modifications by Diel [Ref. 5] allowed the user to save matrices for subsequent runs of the OPTSYSX program, and formed data file sets for the time response program OPTCALC.

The intent of this thesis work was to develop an interactive program to plot the Pole-Zero map, Root-Locus, Bode, Nyquist, and Nichols responses to the open loop, closed loop noise, and compensator transfer functions of a State Variable Control System which has been developed using OPTSYS Program. Mincr modifications to the OPTSYSX Program were necessary to construct a data file sets for plotting the Pole-Zero Map, and in calculations for the Root-Locus, Bode, Nyquist, and Nichols plots.

It is assumed that the user is familiar with the basic concepts of Control Theory and Optimal Systems Design. The symbol/naming conventions of Bryson [Ref. 6]. are used in the discussion of program operations and descriptions of problems using the OPISYS System.

An overview of the OPTSYSX Program capabilities and of modifications to the existing programs is presented first. This is followed by a description of the program (OPTGRAPH), which was developed to plot the Pole-Zero Map and to perform calculations for the Root-Locus, Bode, Nyquist, and Nichols plots.

This work concludes with examples of various types of problems demonstrated in the interactive mode, including a copy of each terminal session with the final results. Complete program listings for the OPTSYS EXEC program, CPTSYSX program, and CPTGRAPH program are included in appendices A,B, and C respectively.

II. THE OPTSYSK COMPUTER PROGRAM

A. BACKGROUND

OPTSYSX is a double-precision, interactive FORTRAN program employing modern control theory analysis techniques. Its capabilities include the calculation of the cren-loop eigensystem, and the stationary closed loop system; the synthesis of regulators and filters; along with power spectral density, and modal distribution computations. The modifications introduced to the OPTSYSX program by this thesis work do not affect the program's original capabilities.

B. OVERVIEW

OFTSYSX is an extremely large and complex program with over 3000 lines of code. To use the program in its small version (dimensioned for a 32 X 32 "F", "G", and "H" matrices), the user must extend his Virtual Machine (VM) memory capacity beyond the default VM memory capacity of 720 kilobytes to 1024 kilobytes.

Any significant increase in the OPTSYSX program size, with the the resulting requirement for additional memory capacity, would cause user difficulties. For this reason the task of obtaining the Pole-Zero maps, Root-Locus, and Bode, Nyquist, Nichols plots for the open loop, noise and compensator transfer functions was relegated to a separate program (OPTGRAPH). Three data files (OPTGROL DATA, OPTGRNO DATA, and OPTGRCM DATA), containing the open loop, noise, and compensator transfer functions, are formed by the OPTSYS program to be transfered to the OPTGRAPH program. The OPTSYS EXEC program provides an interface between the

OPTSYSX program, the time response programs (OPTCALC and OPTPLCT), and the OPTGRAPH program.

C. OPTSYSX MODIFICATIONS

CFTSYSX program modifications consist of the addition of write statements, three flags, and a short routine to interpret user inputs.

Write statements, to input data to the OPTGROL, CPTGRNO, and CPTGRCM DATA files were added to the main program, subroutine INNER, subroutine ZEROS, and subroutine POLES. System information consisting of number of states (Ns), number of controls (Nc), number of measurements (No), number of process noise scurces (Ng), type transfer function (ITFX), Markov Parameter (IE), and two flags to be used by the CPTSYS EXEC and the OPTGRAPH programs is inputed from the main program. The write statements added to the subroutine INNER, and subroutine POLES input the poles for the open loop and noise transfer functions, and compensator transfer function respectively. The zeros, the numerator order, the gain, and the input and output numbers for all three transfer functions are obtained from the subroutine ZEROS.

The first of the two flags, input with the system information from the main program to the three data files, serves as a marker for the CPTSYS EXEC to locate the correct data line for reading system inputs. The second flag, which is set by the routine to interpret user inputs, serves as a signal for the OPTSYS EXEC to either load the OPTGRAPH program if any one of the three transfer functions was calculated by the OPTSYSX program, and abort loading the OPTGRAPH program if none of the three transfer functions were calculated. The third flag (ITFX) is an existing OPTSYSX program flag. The flag (ITFX) is passed from the

subroutine TF to the subroutine ZEROS to identify the calculation of either an open loop, noise, or compensator transfer function zeros.

The short routine added to the main program of OPTSYSX reads the flags ITF1, ITF2, ITF3, and IRET. The flag sent to the OPTGROL, OPTGRNO, or OPTGRCM DATA files is set to allow loading of transfer function data file to the OPTGRAPH program if the user selects either of the transfer function options number two (calculate poles, residues, and zeros -ITF1 = 1, ITF2 = 1, or ITF3 = 1) number three (calculate poles, and zeros - ITF1 = 2, ITF2 = 2, or, ITF3 = 2) when calculating the open loop, noise, or compensator transfer functions. The selection of any other transfer function option will not calculate the transfer function zeros. flag IRET is read to determine if the user desires to rerun a problem without exiting the OPTSYSX program. Should the user elect to rerun a problem without exiting OPTSYSX (IRET = 1), the three data files are set back to the beginning (REWIND) to accept the new problem system data.

D. OPTSYS EXEC MODIFICATIONS

The OPTSYS EXEC was written by Diel [Ref. 5] to interface between the OPTSYSX program and the time response programs OPTCALC and CPTPLOT. The modifications to the exec program were to add the option to select running the OPTGRAPH program to the exec menues and a short section to interface the OPTGRAPH program with the OPTSYSX program.

The added section to interface between the OPTSYSX and OPTGRAPH programs defined loader size (LDRTBLE), file definitions (FILEDEF), and text libraries (TXTLIB) for the CPTGRAPH program. The first line of the three data files is read to ensure that there has been at least one of the three transfer functions calculated by the OPTSYSX program prior to loading OPTGRAPH program.

The OPTSYS EXEC routine is also used to send plots to the VERSATEC plotter from the OPTPLOT program and the OPTGRAPH program.

III. THE OPGRAPH PROGRAM

A. PROGRAM OVERVIEW

OPTGRAPH is an interactive FORTRAN program which uses the transfer function poles and zeros calculated by OPTSYSX to calculate, tabulate, and plot the Pole-Zero Map, Fode, Nyquist, Nichols, and Root-Locus responses for either the open loop, closed loop noise, or compensator transfer functions.

1. Program Language

CPTGRAPH is programmed in FORTRAN following the conventions of the IBM System /360/370/ FORTRAN IV language. CPTGRAPH has been compiled and run under both FORTRAN IV (G1) and FORTRAN H (extended) compilers on the IBM 3033.

2. Graphics Package

This program uses the Display Integrated Software System and Plotting System Software (DISSPLA) developed and distributed by the Integrated Software Systems Corporation (ISSCC) of San Diego, California. The DISSPLA package is a library of FORTRAN subroutines using FORTRAN IV conventions.

3. <u>Library Subroutines</u>

CPTGRAPH uses the International Mathematical and Statistical Library (IMSL) subroutine ZRPOLY to calculate the roots of a polynomial equation. ZRPOLY is a double precision FCRTRAN subroutine to which is input a polynomial with real coefficients (double precision) in terms of decreasing powers of the polynomial. The subroutine finds the rocts of the polynomial and returns a double precision

complex array containing the roots. ZRPOLY is capable of accepting polynomials greater than 0 order and less than 101 order.

4. Program Composition

CPTGRAPH has one main program and 24 subroutines. The main program and its subroutines may be divided into four tasic categories:

- 1) File Data Input
- 2) Interactive Data Input
- 3) Plot Setup and Sequencing
- 4) Calculation

A brief and general description of the program and its subroutines will follow in subsequent sections.

B. GENERAL PROGRAM OPERATION

OFTGRAPH was written to satisfy two specific objectives. The first is to create a program to be used as a instructional tool for students taking controls related courses, and the second is as method to assist in the analysis of actual large order control system problems.

To accomplish these objectives the emphasis while writing this program was to make the program as user oriented as possible by attempting to eliminate ambiguities and providing features which would protect the user from inadvertent wrong entries. An effort was also made to minimize the Virtual Machine (VM) memory required to execute the program to facilitate the analysis of a large order system.

1. User Protection Features

Three basic methods were used to protect the user from an abnormal program termination in the case of an inadvertent wrong entry. The first was to construct the

subroutines to display a summery of the user inputs and allowing changes prior to leaving the subroutine. For the case where the user input is expected to fall within a given range, the input is examined and the user is either allowed to continue for an input within the range or issued an error or warning and reasked the question for an input outside the The final method is used by the three subroutines which read the user input from the screen. The subroutines RDREAL, and RICHAR expect an integer input, number input, and a logical "yes" or "no" respectively. In the event that a "null" line is inadvertently entered, the user is issued a warning and allowed another opportunity to enter the the correct input before abnormally terminating the program. The entry of two "null" lines also offers the user the option to to exit the OPTGRAPH program at other than normal program exit points. The subroutine RDCHAR also examines the input and issues a warning if the input is not either "yes" or "no".

2. <u>large Order System</u>

The large order control problem being considered for analysis by the OPTSYSX and the OPTGRAPH programs is the X-29A aircraft longitudinal axis backup mode system. This system has a (98 X 98) "F" matrix, a (2 X 98) "H" matrix, and a (98 X 1) "G" matrix.

To accommodate this large order system the OPTGRAPH program was dimensioned to accept a system with a maximum of 99 states (Ns), 12 controls (Nc), 12 process noise sources (Ng), and 12 measurements (No). The Virtual Machine (VM) memory requirements for the program were minimized by the reuse of memory locations allocated for storage of calculated data after that data has been either tabulated or plotted. This method of memory reuse has allowed the OPTGRAPH program to be dimensioned to accommodate a large

order system and still operate with less than the 1024 KILOBYTES VM memory required to run OPTSYSX in its small version.

C. SYSTEM/MODEL DESCRIPTION

The system equations used by the OPTSYSX program for the calculation of the transfer functions are of the state variable form. The system equations are:

system model

$$xdot = [F]*x + [G]*u + [GAM]*w$$
 (3.1)

measurement equation

$$z = [H]*x + [D]*u + v$$
 (3.2)

estimator equation

$$xedot = [F]*xe + [G]*u + [K]*(z - [H]*xe)$$
 (3.3)

open loop transfer function

$$[H]*[S[I] - [F]]^{-1}*[G]$$
 (3.4)

closed lcop noise transfer function

$$[H]*[S[I] - [F]]^{-1}*[Gam]$$
 (3.5)

compensator transfer function from measurement to input

$$[C]*(Is[I]-[F]+[G]*[C]+[K]*[H]]-1)*[K]$$
 (3.6)

where

- w = White process noise vector (Ng X 1)
- x = State vector (Ns X 1)
- xdot = Derivative of the state vector (NS X 1)
- y = Output vector (No X 1)
- z = measurement vector (No X 1)
- [C] = control gain matrix (Nc, Ns)
- [D] = control feed-forward distribution matrix (Nc, Nc) of the control vector (u)
- [F] = open-loop dynamics matrix (Ns, Ns)
 (System matrix or Plant matrix)
- [G] = control distribution matrix (Ns, Nc)
- [GAM] = state disturbance distribution matrix (Ns, Ng)
 - [H] = measurement distribution matrix (No, Ns)
 - [I] = identity matrix (Ns, Ns)

D. PROGRAM ORGANIZATION

1. Main Program

The main program presents a menu allowing the user to select for analysis either the open loop transfer function, the closed loop noise transfer function, the compensator transfer function, or exit the OPTGRAPH program. The data file for the selected transfer function is examined by the main program to ensure that the file contains the required transfer function data. Should the data file be incomplete the program gives the user a warning message indicating the nature of the missing data and allows the user to select another option.

The main program menu:

OPIGRAPH

DO YOU DESIRE TO ANALYZE:

- 1. OPEN LOOP TRANSFER FUNCTION
- 2. NOISE TRANSFER FUNCTION
- 3. COMPENSATOR TRANSFER FUNCTION
- 4. EXIT OPTGRAPH

ENTER OPTION NUMBER.

Data is read from the selected file by the main program and formed into three arrays and seven integer variables. The exchange of data between the main program and the subroutines, and between the subroutines is by the extensive use of labeled common statements. The data transfered through the subroutine call statements is limited primarily to flags, and constants. The program moves to its primary sequencing subroutine (GRAPH) upon the completion of file data entry.

2. <u>Program Sequencing</u>

The subroutine GRAPH first presents the user with a summary of the the transfer system received from the data file. The user is then asked which transfer function he desires to to analyze using the conventions of the OPTSYSX program describing the transfer functions by input number and output number. A menu is presented which allows the user to select graphical and/or tabular system response (Pole-Zero map, Root-locus, Bode, Nyquist, or Nichols), select another transfer function, or exit the OPTGRAPH program. Upon completion of a graphical and/or tabular response option, or change of transfer function option, the program returns to the GRAPH menu to allow the user to choose another option or exit to the main program.

Subroutine GRAPH data summary and menu:

OPIGRAPH

THE OPEN LOOP TRANSFER SYSTEM OBTAINED FROM OPTSYS CONTAINS:

4

1. NUMBER OF STATES =

- 2. NUMBER OF CCNTROLS (INPUTS) = 1
- 3. NUMBER OF MEASUREMENTS (OUTPUTS) = 1

- 7. ANOTHER TYPE TRANSFER FUNCTION /EXIT OPTGRAPH ENTER OPTICN NUMBER.

3. <u>Graphic and/or Tabular System Response</u>

The selection of a graphical and/or tabular system response option for an Pole-Zero map, Root-Locus, Bode, open loop Nyquist, or open loop Nichols calls the subroutines

PZERO, RTLO, BODE, NYQST, or NICHOL respectively. While the response of these subroutines is different, their crganization is similar.

The subroutines PZERO, RTLO, BODE, NYQST, and NICHOL primarily act as sequencing and plot setup subroutines. The interactive questioning of the user for graphic/tabular response information and the system response calculation has been relegated to other subroutines. The subroutines PZERO, RTLO, BODE, NYQST, and NICHOL are divided into two major sections with the first being devoted to producing a graphical output and the second to producing a tabular output.

The user is presented a subroutine menu offering the cption for graphic response, tabular response, or exiting the subroutine. The program moves to either the first section (graphic response), second section (tabular response) or back to the subroutine GRAPH menu depending on the option selection. The program returns to the subroutine menu upon completion of the of either the graphic response, or tabular response section, allowing the user to select another response option, or exit the subroutine.

Features that are common to the five subroutines will be described here and features that are unique to one of the subroutines will be described in the following section under the appropriate response heading.

For a graphic response, the user is given the choice of two printer options (TEK 618, or VERSATEC). With the selection of the TEK 618, the plot page size is defaulted to 11 inches by 8.5 inches, and the plot will be presented on the TEK 618 screen. The VERSATEC option gives the user the option to create up to a 21 inch by 21 inch plot (maximum for the VERSATEC printer) and causes a DISSPLA METAFILE to be created. A scaling subroutine (PSCALE) scales the plot heading, legend, etc. in proportion to the page width selected. The VERSATEC option offers the the advantage of a

high quality print from the VERSATEC printer using the VERSATEC printer option in the OPTSYS EXEC. The creation of a DISSPLA METAFILE also gives the user (after he exits optsys) the opportunity to use printers other than the TEK 618 or VERSATEC. A major disadvantage with the VERSATEC option is that the user must exit the OPTGRAPH program before he can print a graphic system response. For this reason, it is recommended that the system response first be plotted on the TEK 618 prior to selecting the VERSATEC option.

For a tabular response, the user is presented a menu which gives him the choice of three devices (screen, printer, or disk) to send the tabular output. The user is asked if he desires to make any changes, after the tabular data has been calculated. If the answer is affirmative, he is presented a menu and allowed to make changes and rerun the tabular data routine.

Examples of these features are included in the following sections with the interactive examples for the system responses.

E. INTERACTIVE EXAMPLES

The open-loop, closed loop noise, and compensator transfer functions are are handled identically by the OPTGRAPH program, with the only difference being the program and graph headings identifying the transfer function type. The frequency response programs for the Bode, Nyquist, and Nichols responses use identical setup and tabular data routines.

A good overall representation of the OPTGRAPH program capabilities will be demonstrated by single interactive terminal session examples for the pole-zero, root locus, and bode responses using selected transfer functions. Tabular

data examples will be provided for the Pole-Zero, Root Locus, and Bode responses, and graphic response examples will be provided the Fole-Zero, Root Locus, Bode, Nyquist, and Nichcls responses.

F. CHARACTERISTIC EQUATION ANALYSIS

The subroutines PZERO and RTLO are similar in their basic formats. The pole and zero locations for the selected transfer function input and output numbers are read into two single dimension arrays. The extraneous zeros, calculated by the OPTSYSX program, are eliminated by comparing the zeros to the Markov parameter sent with the system information from the OPTSYSX program. For a graphical response, the user is asked to define the plot limits in terms of X-coordinates (real axis) and Y-coordinates (imaginary axis). Points for the plot which fall outside these limits will be ignored. System information (tranfer function input number, output number, and (DC) gain) is listed in the graph legend.

1. Pole-Zero Map

The subroutine PZERO converts the double precision numbers for pole and zero locations to single precision for compatibility with the with the Graphics Package and plots the poles and zeros within the plot limits defined by the user for the graphical response routine. For tabular data response the user is given system information (numerator order, denominator order, and transfer function (DC) gain) for the selected transfer function input number and output number, and the pole and zero locations.

2. Fole-Zero Mar (Interactive Example)

The following example of a simplified open loop transfer function for an airplane with an autopilot in the longitudinal mode was obtained from [Ref. 7,p.315].

The aircraft system is represented by:

[D] = [0]

$$[GAM] = [0]$$

$$[H] = [1. 0. 0. 0.]$$

3. Root-Locus

(with negative unity feed-back) from the selected transfer function input numbers and output numbers. Transfer function poles and zeros are formed into two separate polynomials by the subroutine MAKPOL. The numerator polynomial (zeros) is multiplied by the gains, and the two polynomials are added to form a single polynomial. Complex roots of the of the polynomial are calculated by the IMSL library subroutine ZRPCLY. The complex roots are separated into real and imaginary components for either plotting or tabulating.

The plotting routine first plots the transfer function pole and zero locations then plots the root locations as they are received from the subroutine ZRPOLY. For the plotting routine the gain interval specified by the user is divided into 2000 evenly spaced points for the subroutine ZRPOLY to calculate roots. The poles, zeros, and roots are plotted within the plot limits specified by the user.

For the tabular data routine the user is given the option to choose between 1 and 500 points for the subroutine ZRPOLY to calculate roots. The tabular data output provided for the user is system information (numerator order, denominator order, and transfer function (DC) gain) for the selected transfer function input number and output number, the pole and zero locations, and the root locus gains and roots

A positive unity feedback system may be analyzed by specifying a negative gain range vice a positive gain range.

G. FREQUENCY RESPONSE ANALYSIS

The calculations for the frequency response of the Bode, Nyquist, and Nichols responses are identical. The only difference is in the graphical presentation of the calculated data. The subroutines BODE, NYQST, and NICHOLS call the subroutine FREQ to calculate the transfer function magnitude and phase for the frequency range specified by the user.

The subroutine FFEQ eliminates the extraneous zeros by comparing the zeros to the Markov parameter as described in the Characteristic Equation Analysis section. The frequency response magnitude and phase are calculated using double precision complex library functions following the

conventions of the IBM System /360/370/ FORTRAN IV language. The frequency response is calculated by determining the product of successive numerator zeros which combined with the frequency and divided by the product of successive denominator poles which also have been combined with the frequency. The magnitude for the complex result of the zeros, poles, and frequency calculations is determined using the FORTRAN dcuble precision library functions for finding the magnitude of a complex argument. The phase of the of the complex result is determined by separating the real and imaginary parts of the complex results, and finding the phase angle using the double precision FORTRAN library function arctangent. The angle is converted from radians to degrees and is corrected for proper quadrant by checking the signs of the real and imaginary parts. The normal range for calculating phase angles by the subroutine is from +540 degrees to -540 degrees. This range is considered adequate for most application, but should these limits be exceeded the plot will jump with a vertical line to either +360 degrees or -360 degrees respectively before continuing with the plot.

For a graphic response the user specified frequency range is divided into 500 equally spaced points (on a logrithmic scale) for which to calculate the magnitude and phase. The user is given the option to select between 1 and 500 points for tabular data.

1. <u>Pode Response</u>

The graphic response section of the subroutine BODE creates two plots. The first plot is the response magnitude in decibels versus the frequency in radians per second. The magnitude from the subroutine FREQ is converted to decibels and plotted with its corresponding frequency. The second plot is of the phase in degrees versus frequency in radians

per second. The phase from the subroutine FREQ is plotted with its corresponding frequency. The frequency for both plots is plotted on a logrithmic scale. The scale range for both is set automatically to include the entire range of data to be plotted by the subroutine MINMAX which scans the data for the maximum and minimum values. System information (tranfer function input number, output number, and (DC) gain) is listed in the graph legend.

The magnitude in decibels and the phase in degrees is searched for "0" decibel and 180 degree crossover points to calculate the phase and gain margins.

The tabular response section gives the user the option to select the the number of frequency points to be calculated between 1 and 500 for the frequency range he has specified. For tabular data response the user is given system information (numerator order, denominator order, and transfer function (DC) gain) for the selected transfer function input number and output number, and the frequency (radians per second), magnitude (decibels), phase (degrees), and the real and imaginary frequency response parts.

2. Bode Response (Interactive Example)

The following example of compensator transfer function with a filter and regulator was obtained from [Ref. 8,pp. 382 - 384].

The compensated system is represented by:

$$[F] = [0. 1.0]$$

$$[G] = [0.787]$$

$$[GAM] = [0.1]$$

$$[H] = [1. 0.]$$

$$[K] = [95.4]$$

$$[Q] = [10.]$$

END RECORDING OF TERMINAL SESSION

The preceding example follows at the end of the chapter as figure 3.3 and figure 3.4.

b. Example of Tabular Data Listing File

The terminal session for the Bode tabular data response is similar to the Bode graphic response terminal session. Appendix D contains an example of tabular output sent to a disk (OPGRAPH LISTING) for five points between 10 and 100 radians/second.

3. Nyquist Response

The graphic response section of the subroutine NYQST creates a polar plot from the magnitude and phase data received from the subroutine FREQ. The plot is automatically scaled from a minimum radius of one by using the

subroutine MINMAX to determine the maximum phase and magnitude values. The gain / phase margin calculations and the tabular data output are identical to the subroutine BODE.

4. Nyquist Response (Interactive Example)

The following example is of the open loop transfer function for the filter simulation example described in the Bode interactive section.

This example follows at the end of the chapter as figure 3.5.

5. Nichols Response

The graphic response section of the subroutine NICHCI creates a single rectangular plot of magnitude in decibels versus phase in degrees. The magnitude from the subroutine FREQ is converted to decibels and plotted with the corresponding magnitude. The plot is automatically scaled using the subroutine MINMAX to determine the maximum phase and magnitude values. The gain / phase margin calculations and the tabular data output are identical to the subroutine BODE.

6. Nichols Response (Interactive Example)

The following example is of the open loop transfer function for the filter simulation example described in the Bode interactive section.

This example follows at the end of the chapter as figure 3.6 .

Figure 3.2 Root Locus Response Example.

Figure 3.4 Bode Response Example (Phase).

Figure 3.6 Nichols Response Example.

IV. CONCLUSIONS AND RECOMMENDATIONS

A. CCNCLUSIONS

An evaluation of the computational ability of OPTSYSX and CPTGRAPH, the program was tested using an 82 X 82 matrix, provided by NASA-Edwards, of longitudinal equations for the X-29A experimental forward-swept wing fighter aircraft prototype. The OPTSYSX program array had to be redimensioned and a 2-megabyte virtual machine size was required for a system of this size.

The open loop eigenvalues calculated by the OPTSYSX program compared favorably with the Eigensystem data supplied by NASA-Edwards, but the OPTSYSX program failed in calculating the open loop transfer function zeros. Extraneous zeros (calculated by OPTSYSX) were of the same approximate magnitude as the open loop system zeros. This prevented the identification and elimination of the extraneous zeros by comparison with the Markov parameter. The open loop zero identification was further complicated by not having available open loop transfer function zero information from NASA-Edwards to compare the OPTSYSX results to.

When requested for additional information NASA-Edwards provided a computer tape with a revised 98 X 98 matrix of longitudinal motion equations for the X-29A fighter aircraft. For this revised system, the OPTSYSX program requires a virtual machine size in excess of 2-megabyte. Time constraints have prevented running the OPTSYSX program with the revised system.

The OPTGRAPH program was tested using the OPTSYSX program's open loop Eigenvalue and transfer function cutput data for the X-29A 82 X 82 system of longitudinal motion

equations. OPTGRAPH provided excellent quality Bode plcts for all of the open loop transfer function inputs and outputs and did not exhibit any computational difficulties as indicated by the lack of error messages at the end of the test. While the test results are encouraging as to the ability of the OPTGRAPH program to assist in the analysis of large order systems, the actual computational accuracy of the OPTGRAPH program can not be fully verified until accurate transfer function information can be obtained from the OPTSYSX program.

B. RECCMMENDATIONS

Based on the results of this Thesis the following areas emerged as possible areas for further research and study.

1. Root Finding Routines

The OPTSYSX program has two similar root finding subroutines (HQR and HQR2), to find the transfer function Eigensystem (poles) and zeros. The order of the transfer function numerator is calculated separately in the subroutine ZEROS.

The inclusion of the open loop transfer function eigensystem (pole locations), zero locations, transfer function numerator orders, and transfer function gains, for the revised (98 X 98) longitudinal mode system by NASA-Edwards should simplify the locating the problem in calculating the transfer function zeros.

The open loop system data from NASA-Edwards also included Bode magnitude and phase plots, and gain and phase margin information, which can be used to evaluate more conclusively the OPTGRAPH program's ability to help evaluate a large order system.

2. Program Memory Requirements

The OPTSYSX program requires in excess of 2-megabyte of virtual machine memory when configured for large matrix operations (98 X 98). Virtual machines with this memory capacity are not normally available to a user. The memory usage for matrix storage and manipulation is a possible area for the reduction in program memory requirement size. The OPTSYSX program retains most of its computational arrays in memory. This method simplifies programming but is extremely inefficient in its use of virtual machine memory.

3. Further Modifications

The area of modern digital controls should be further investigated. The computational abilities of the OPIGRAPH program make it readily adaptable, with minor modifications, for assisting in the analysis of transfer functions in the digital domains.
